

Supplementary information 3

Korner-Nievergelt, Liechti, Thorup (2013): “A bird distribution model for ring recovery data: Where do the European robins go?”

This document contains two figures that show the 95% credible intervals of all proportions presented in the barplot of Fig. 2 of the main text.

Fig. S3a. Estimated proportions of birds ringed in Fennoscandia during different months (indicated on the left outer axis) being in the four different regions (indicated on the bottom) during 8 different seasons (x-axis). The vertical bars give the 95% CrI. Grey scales proportional to the overlap between prior and posterior distribution. White (invisible) means that the posterior equals the prior (no information in the data). Darker gray corresponds to more data-informed estimates.

Fig. S3b. Legend as in Fig. S3a but for birds released in central Europe.
